

# **Search algorithms: UCS and A\***

Devika Subramanian

# Route planning

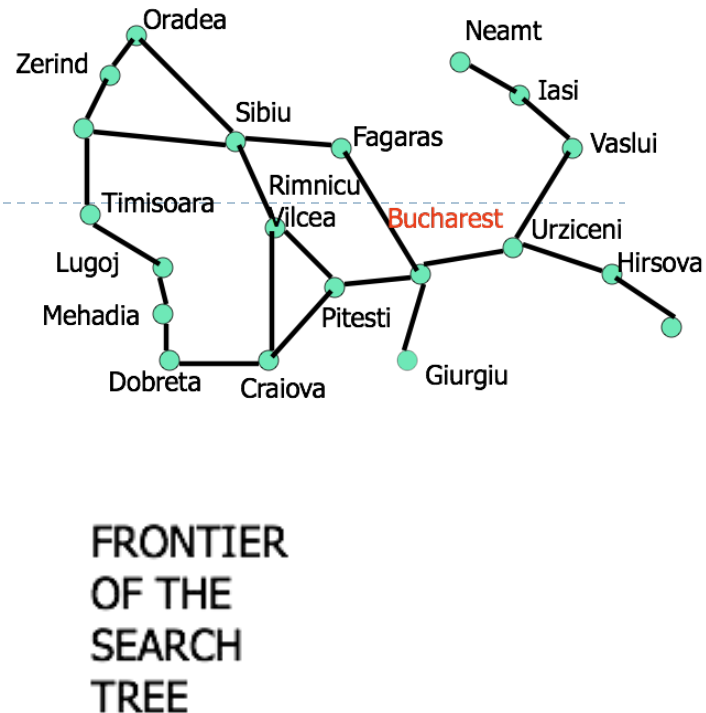

# Need for search algorithms

---

- ▶ Dynamic programming takes time proportional to the **square** of the size of the state space.
  - ▶ It finds shortest paths to a goal (e.g., Bucharest) from **every** node in the state space (e.g., every city in Romania).
- ▶ What if all we care about is getting between **a given node** (e.g., Arad) and **a goal node** (e.g., Bucharest)?
  - ▶ Can we solve this problem in time proportional to the size of the state space?
- ▶ This is what search algorithms are for: given a start state, a goal state and a state space graph, find a path between the two states.

# Search tree

A tree is a graph in which any two vertices are connected by exactly one path.

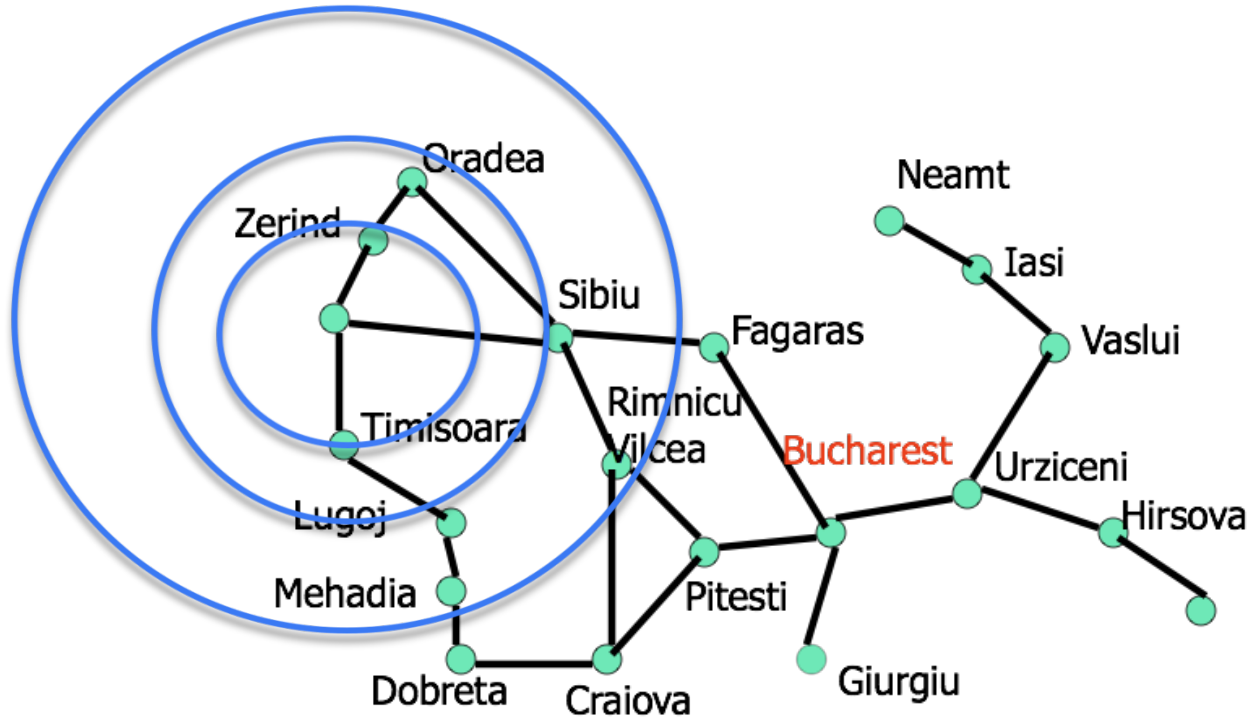

- A what-if tree of plans and their outcomes
- The root node is the start state, children correspond to successor states
- A search frontier and visited list are maintained
- For real problems, we never build the entire tree!

# Search algorithms

---

- ▶ Which node in the frontier of the search tree to expand next?

# Uniform cost search (visual)

Expands nodes in order of increasing cost from start state.  $g(n)$  = distance from start to  $n$

# Uniform cost search

---

- ▶ **Visited nodes** = states for which optimal path from start state is known (key invariant maintained by algorithm)

- ▶ **Unexplored nodes** = states which have not yet been generated
- ▶ **Frontier nodes** = nodes separating the explored from the unexplored, whose successors have not been generated
- ▶ When goal node moves into the visited list, we have found an optimal path from start to goal.

Edge costs  $\text{cost}(\text{current}, \text{nbr})$  are assumed to be  $\geq 0$

## UCS (uniform cost search)

---

- ▶ Function  $\text{UCS}(\text{start}, \text{goal}, \text{graph}, \text{frontier})$  returns True or False
  - ▶ Insert  $(\text{start}, 0)$  into the frontier (priority queue ordered by cost from start).
  - ▶ Initialize the visited list to empty.
  - ▶ while frontier is nonempty:
    - ▶  $(\text{current}, c) = \text{pop}$  node from frontier with lowest cost
    - ▶ add node  $(\text{current}, c)$  to the visited list
    - ▶ If  $\text{current} == \text{goal}$ , return True.
    - ▶ for every nbr of current node
      - If  $(\text{nbr}, c')$  not in frontier or in visited
        - insert  $(\text{nbr}, c + \text{cost}(\text{current}, \text{nbr}))$  into frontier
      - Else if  $c' > c + \text{cost}(\text{current}, \text{nbr})$ 
        - Insert  $(\text{nbr}, c + \text{cost}(\text{current}, \text{nbr}))$  into frontier
        - Remove  $(\text{nbr}, c')$
  - ▶ return False.

# Uniform Cost Search example

- ▶ G1 and G2 are goal nodes, and A is the start node.

# Uniform Cost Search Example

Frontier

Visited

(A,0)

Frontier starts with (A,0).  
Visited is empty.

# Uniform Cost Search Example

Frontier

(B,1)  
(G1,5)  
(G2,7)

Visited

(A,0)

Remove (A,0) from frontier and move it to Visited.

For every nbr of A  
insert (nbr,  $0 + \text{cost}(A, \text{nbr})$ ) into frontier

# Uniform Cost Search Example

Frontier

(C,2)  
(G2,4)  
(G1,5)

Visited

(A,0)  
(B,1)

Remove (B,1) from frontier and  
move it to Visited.

Note: (G2,7) gets deleted  
from frontier because we have  
found a cheaper way via B: (G2,4)

For every nbr of B  
insert (nbr, 1 + cost(B, nbr)) into frontier

# Uniform Cost Search Example

Frontier

(G2,4)  
(G1,5)

Visited

(A,0)  
(B,1)  
(C,2)

Remove (C,2) from frontier and move it to Visited.

For every nbr of C  
insert (nbr, 2+cost(C,nbr)) into frontier

(G2,5) is not added because (G2,4) is in the frontier.

# Uniform Cost Search Example

Frontier

(G2,4)  
(G1,5)

Visited

(A,0)  
(B,1)  
(C,2)

(G2,4) is the top node and it is a goal node.  
Path found! A—B—G2

# Properties of uniform cost search

---

- ▶ It is complete: if a path exists, uniform cost search will find it.
- ▶ It is optimal: uniform cost search will find a least cost path from start node to a goal node, if one exists.
- ▶ Time complexity =  $O(\text{size of state space})$
- ▶ Space complexity =  $O(\text{size of state space})$

# Optimality of UCS

- ▶ Theorem: when a state  $s$  is popped off the frontier, the cost associated with it is the least cost from the start state to  $s$ .
- ▶ Proof:

# Informed search

---

- ▶ Informed search: use estimates of distance to goal states to direct search.

# Informed search: greedy search

---

- ▶ Idea: minimize estimated cost to reach goal.
- ▶ Define  $h(n)$  = estimated cost of the cheapest path from node  $n$  to a goal state.  $h(n)$  is called the **heuristic function**.
- ▶ We require  $h(n) \geq 0$  for all nodes  $n$ , and  $h(g) = 0$  for all goal nodes  $g$ .
- ▶  $h(n)$  is problem-specific. Example: in maze navigation, Manhattan distance to goal.

# Romania problem revisited

# Heuristic distance estimates for the Romania problem $h(n)$

---

## ► Straight-line distance to Bucharest

- |                |                     |
|----------------|---------------------|
| ► Arad: 366    | Mehadia: 241        |
| ► Bucharest: 0 | Neamt: 234          |
| ► Craiova: 160 | Oradea: 380         |
| ► Dobreta: 242 | Pitesti: 98         |
| ► Eforie: 161  | Rimnicu Vilcea: 193 |
| ► Fagaras: 178 | Sibiu: 253          |
| ► Giurgiu: 77  | Timisoara: 329      |
| ► Hirsova: 151 | Urziceni: 199       |
| ► Iasi: 226    | Zerind: 374         |
| ► Lugoj: 244   |                     |

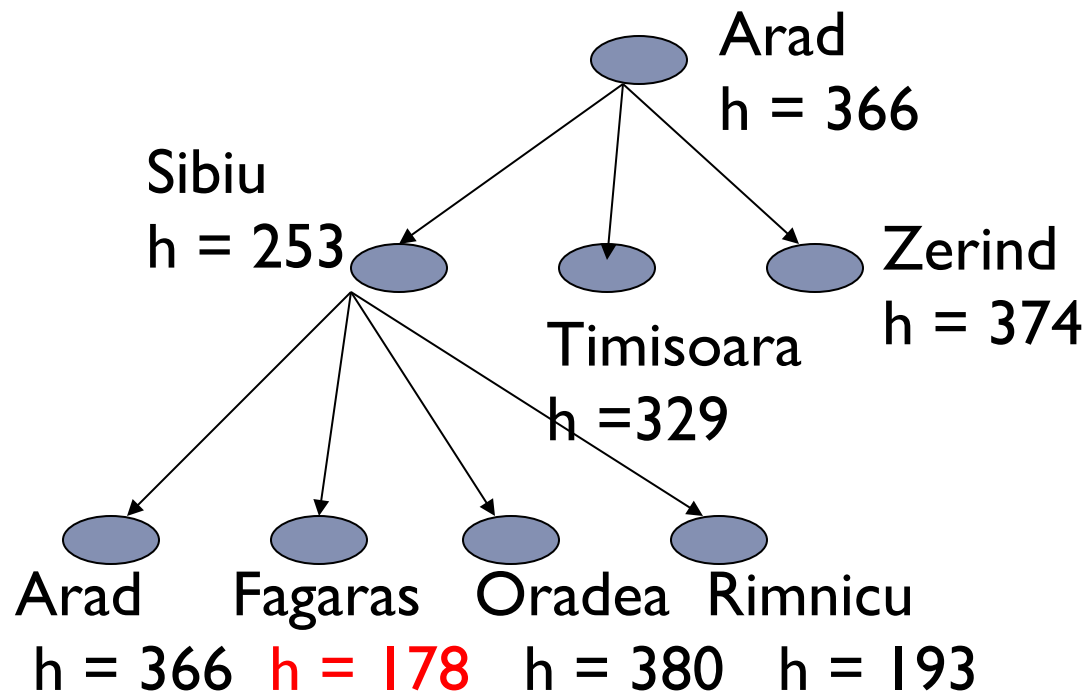

# Greedy search in action

---

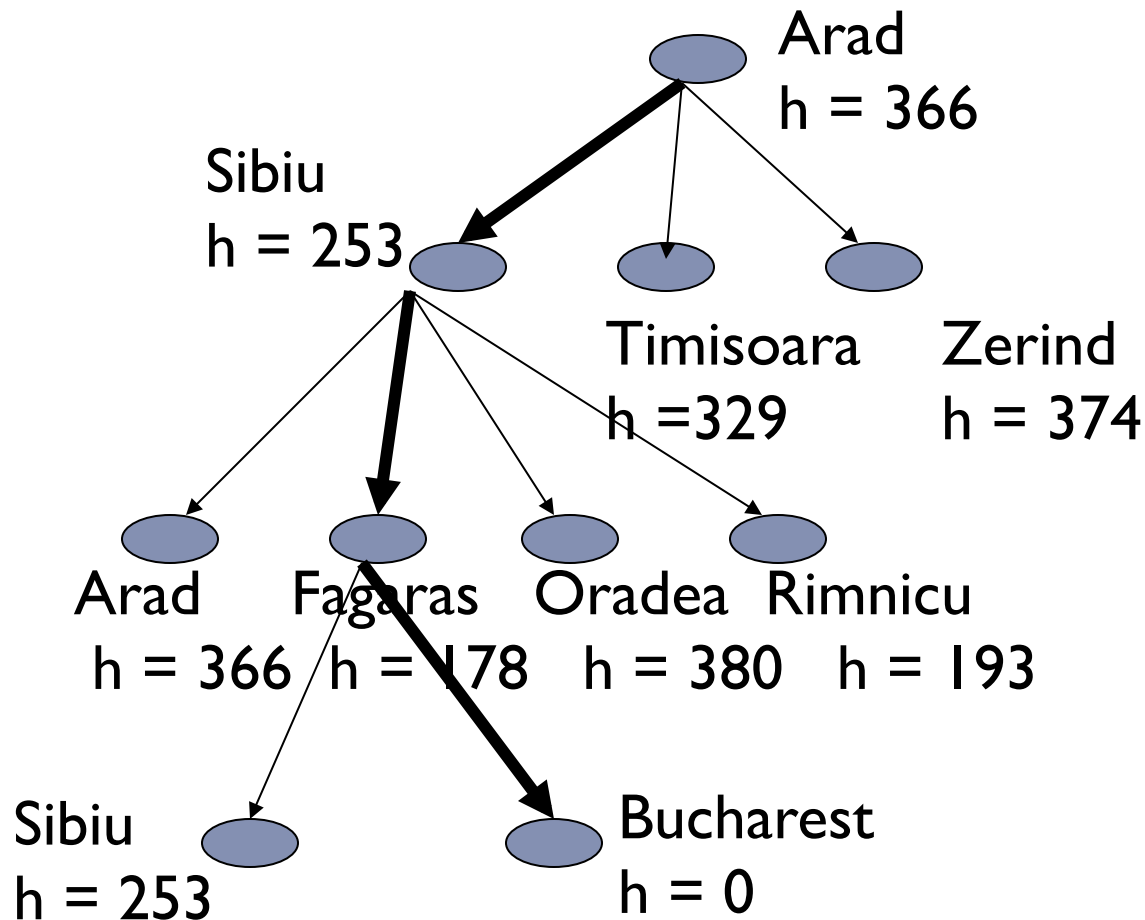

Now expand Sibiu and add its successors to search tree.

# Greedy search in action (contd.)

Fagaras has the lowest  $h$ , so it is the next node to be expanded.

# Greedy search in action (contd.)

Best-first is  
SUB-OPTIMAL!

Goal generated!  
Path found is  
Arad  $\rightarrow$  Sibiu  $\rightarrow$   
Fagaras  $\rightarrow$  Bucharest

# Romania problem revisited

# Properties of greedy search

---

- ▶ It is complete, if visited list is maintained.
- ▶ It is not optimal.
- ▶ Time complexity:  $O(\text{size of the state space})$ .
- ▶ Space complexity:  $O(\text{size of the state space})$ .
- ▶ Actual performance of greedy search is a function of the accuracy of  $h(\cdot)$ .

# What's wrong with greedy search

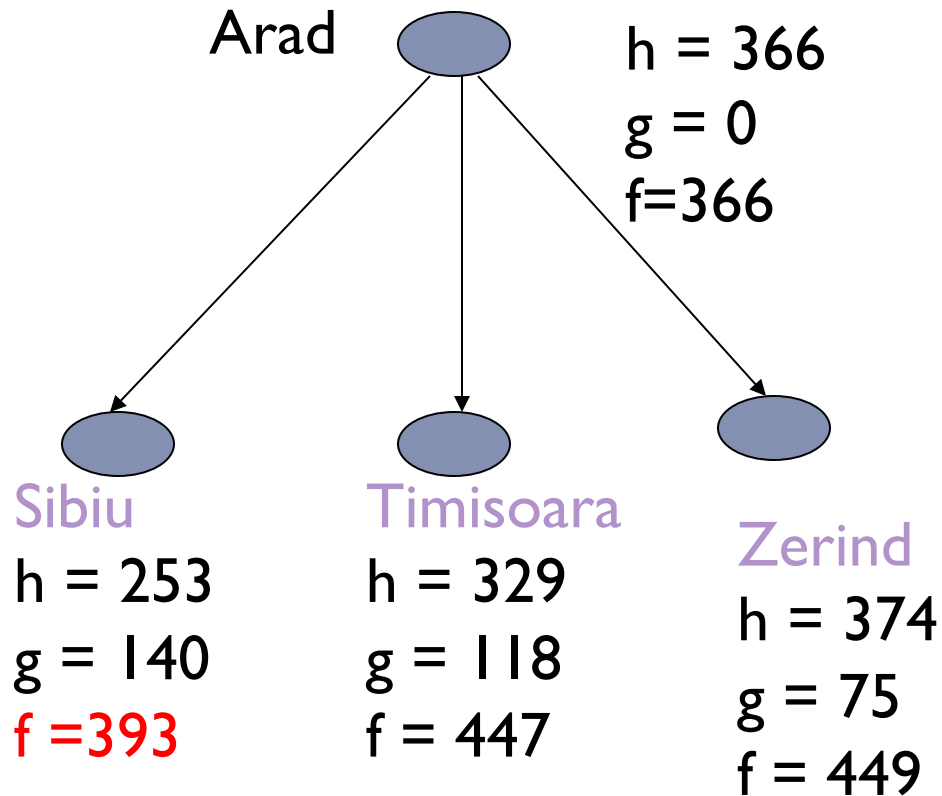

# A\* search

---

- ▶ Uses estimated cost of the cheapest solution path through node  $n$ , as a measure of the merit of node  $n$ .
- ▶  $f(n) = g(n) + h(n)$  where
  - ▶  $g(n)$  = actual path cost from start node to node  $n$ .
  - ▶  $h(n)$  = **estimated** cost of path from  $n$  to closest goal node.
- ▶ A\* additively combines uniform cost search ( $g(n)$ ) and greedy search ( $h(n)$ ).

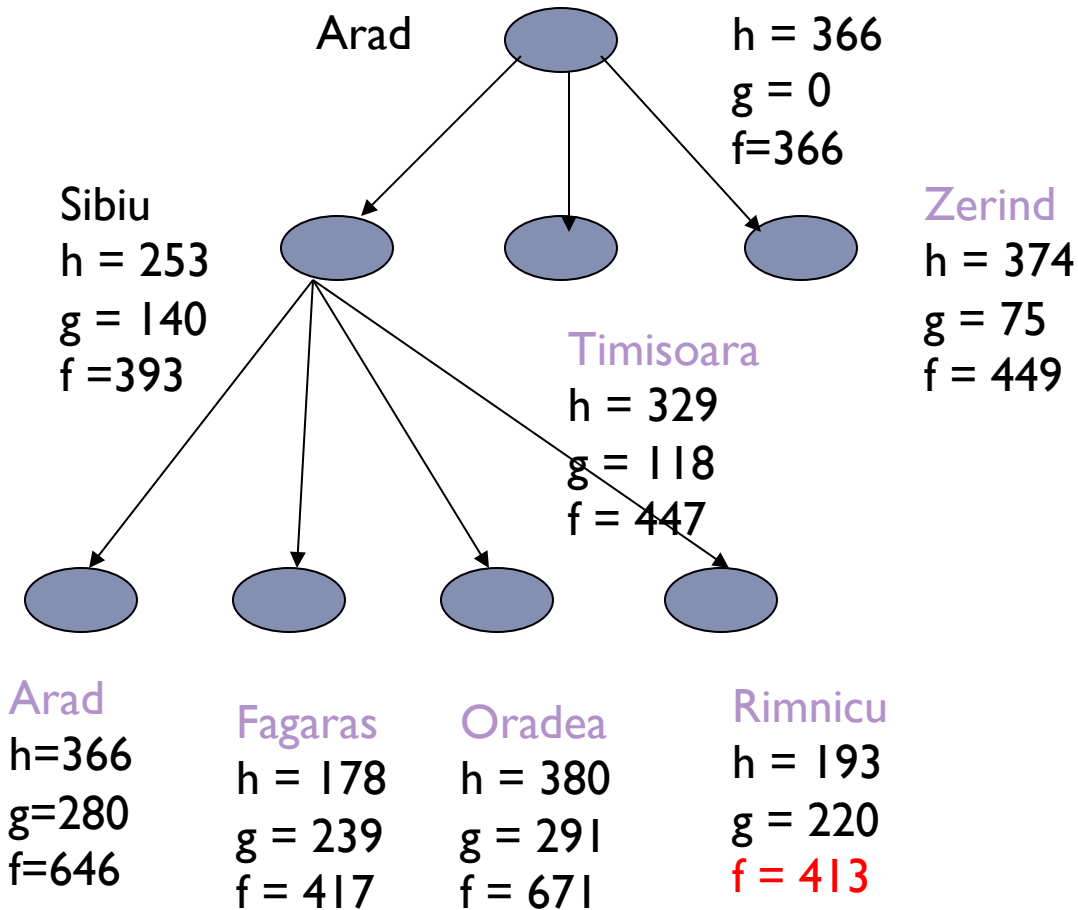

# A\* in action

---

Sibiu will be expanded next.

# A\* in action (contd.)

Rimnicu will  
be expanded  
next.

# How A\* searches

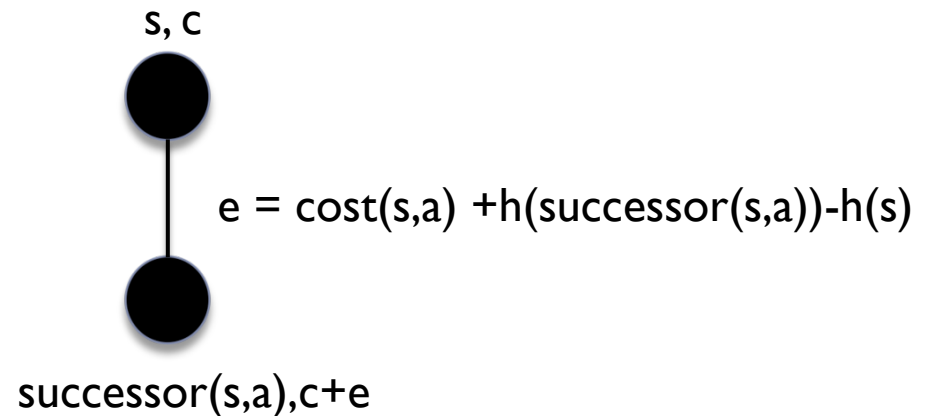

# The A\* algorithm

- ▶ Function  $A^*(start, end, graph, frontier)$  returns True or False
  - ▶ Insert  $(start, 0 + h(start))$  into the frontier (priority queue ordered by  $f() = h() + g()$ ).
  - ▶ Initialize the visited list to empty.
  - ▶ while frontier is nonempty:
    - ▶  $(current, c) = \text{pop}$  node from frontier with least f-cost
    - ▶ add  $(current, c)$  to the visited list
    - ▶ If  $current == end$ , return True.
    - ▶ for every nbr of current node
      - If  $(nbr, c')$  not in frontier or visited
        - **insert**  $(nbr, c + \text{cost}(current, nbr) + h(nbr) - h(current))$  into frontier
      - Else if  $c' > c + \text{cost}(current, nbr) + h(nbr) - h(current)$ 
        - **insert**  $(nbr, c + \text{cost}(current, nbr) + h(nbr) - h(current))$  into frontier
        - Remove  $(nbr, c')$
  - ▶ return False.

# A\* and UCS

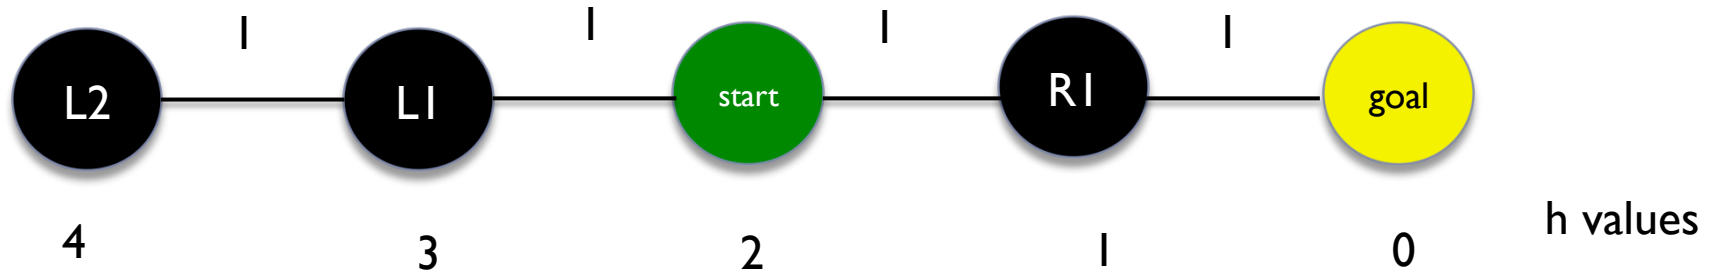

- ▶ We can simulate A\* with UCS by
  - ▶ A\* has priority function  $f(n) = g(n) + h(n)$  while UCS has priority function  $g(n)$ . Cost of start node for UCS is 0, for A\* is  $h(\text{start})$
  - ▶ Simply modify the edge cost:  $\text{cost}(s, a)$  by
    - ▶  $\text{cost}(s, a) + h(\text{successor}(s, a)) - h(s)$

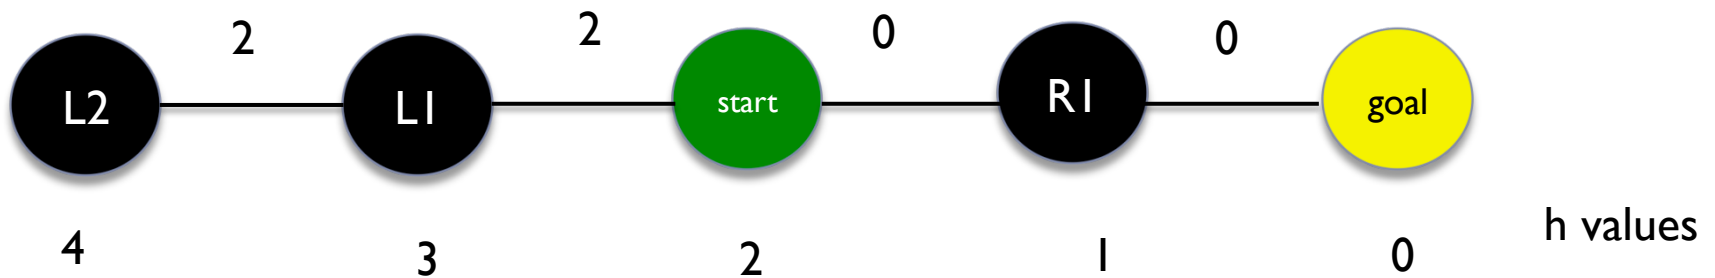

# A\* vs UCS example

## UCS view

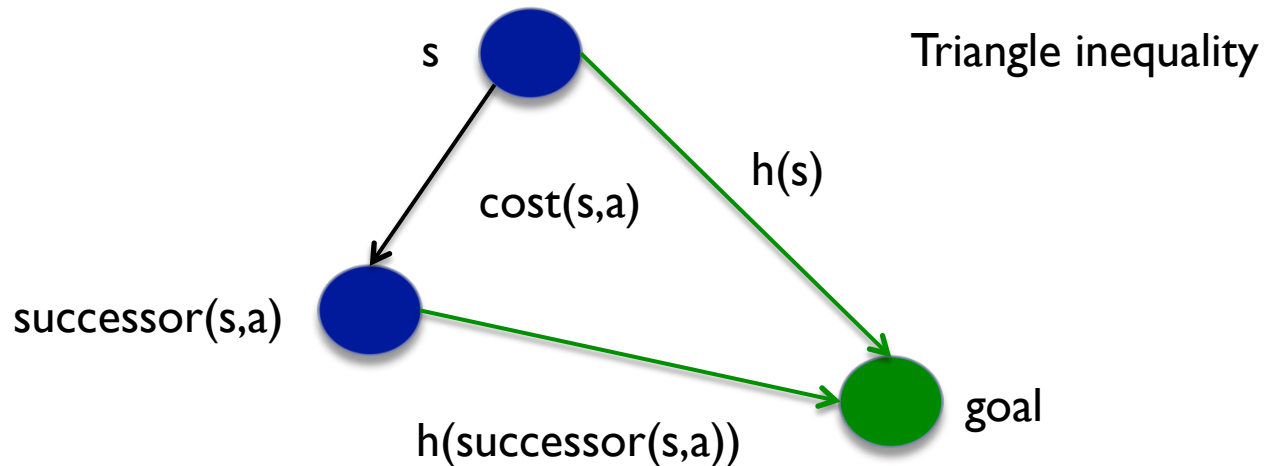

## A\* view

$$\text{cost}(s,a) + h(\text{successor}(s,a)) - h(s)$$

# Consistent heuristic

- ▶ A heuristic  $h$  is consistent if
  - ▶  $\text{cost}(s,a) + h(\text{successor}(s,a)) \geq h(s)$
  - ▶  $h(\text{goal}) = 0$
- ▶  $A^*$  with a consistent heuristic is guaranteed to find the shortest path between a start and goal state.

# A\* properties

---

- ▶ It is complete.
- ▶ It is optimal provided modified edge costs  $\geq 0$ 
  - ▶  $\text{cost}(s,a) + h(\text{successor}(s,a)) - h(s) \geq 0$ , i.e.,  $h$  is consistent
- ▶ Time complexity:  $O(\text{size of state space})$
- ▶ Space complexity:  $O(\text{size of state space})$
- ▶ A\* is optimally efficient – there is no algorithm that expands fewer nodes than A\* with a given  $h$  that guarantees completeness and optimality.
  - ▶ A\* expands all nodes  $n$  with the property that  $f(n) \leq \text{cost of optimal path between start and goal}$
- ▶ A\* runs out of memory before it runs out of time.

# Is this h consistent?

---

# Admissible heuristic

---

- ▶ Let  $h^*(n)$  = the true minimal cost to goal node from  $n$ .
- ▶ We will call  $h$  an admissible heuristic if  $h(n) \leq h^*(n)$  for all nodes  $n$ .
- ▶ An admissible heuristic never overestimates the remaining distance to the goal.
- ▶ An admissible heuristic is optimistic.
- ▶ Designing admissible heuristics is where the work is in using  $A^*$ .

# Consistency and admissibility

---

- ▶ If a heuristic  $h(n)$  is consistent, then it is admissible.
- ▶ Proof: exercise!

# Example of a consistent heuristic

Relax constraints on the original problem. Knock down walls!  
A consistent heuristic for the original problem is an exact solution  
for the relaxed problem. Here  $h(n)$  = Manhattan distance from  $n$  to goal.

# Relaxed problem

---

- ▶  $P'$  is a relaxation of search problem  $P$  if  $P$  and  $P'$  have the same states and actions (same state graph), and edge costs in  $P'$  are lower than those in  $P$ 
  - ▶  $\text{cost}'(s,a) \leq \text{cost}(s,a)$ , for every  $s,a$
- ▶ Given a relaxed search problem  $P'$ , the relaxed heuristic  $h(n)$  for  $P$  is the shortest path from  $n$  to  $g$  in the graph for  $P'$  with reduced cost. It is a consistent heuristic for  $P$ .
  - ▶  $h(s) \leq \text{cost}'(s,a) + h(\text{successor}(s,a))$  [triangle inequality]
  - ▶  $h(s) \leq \text{cost}(s,a) + h(\text{successor}(s,a))$  [relaxation]

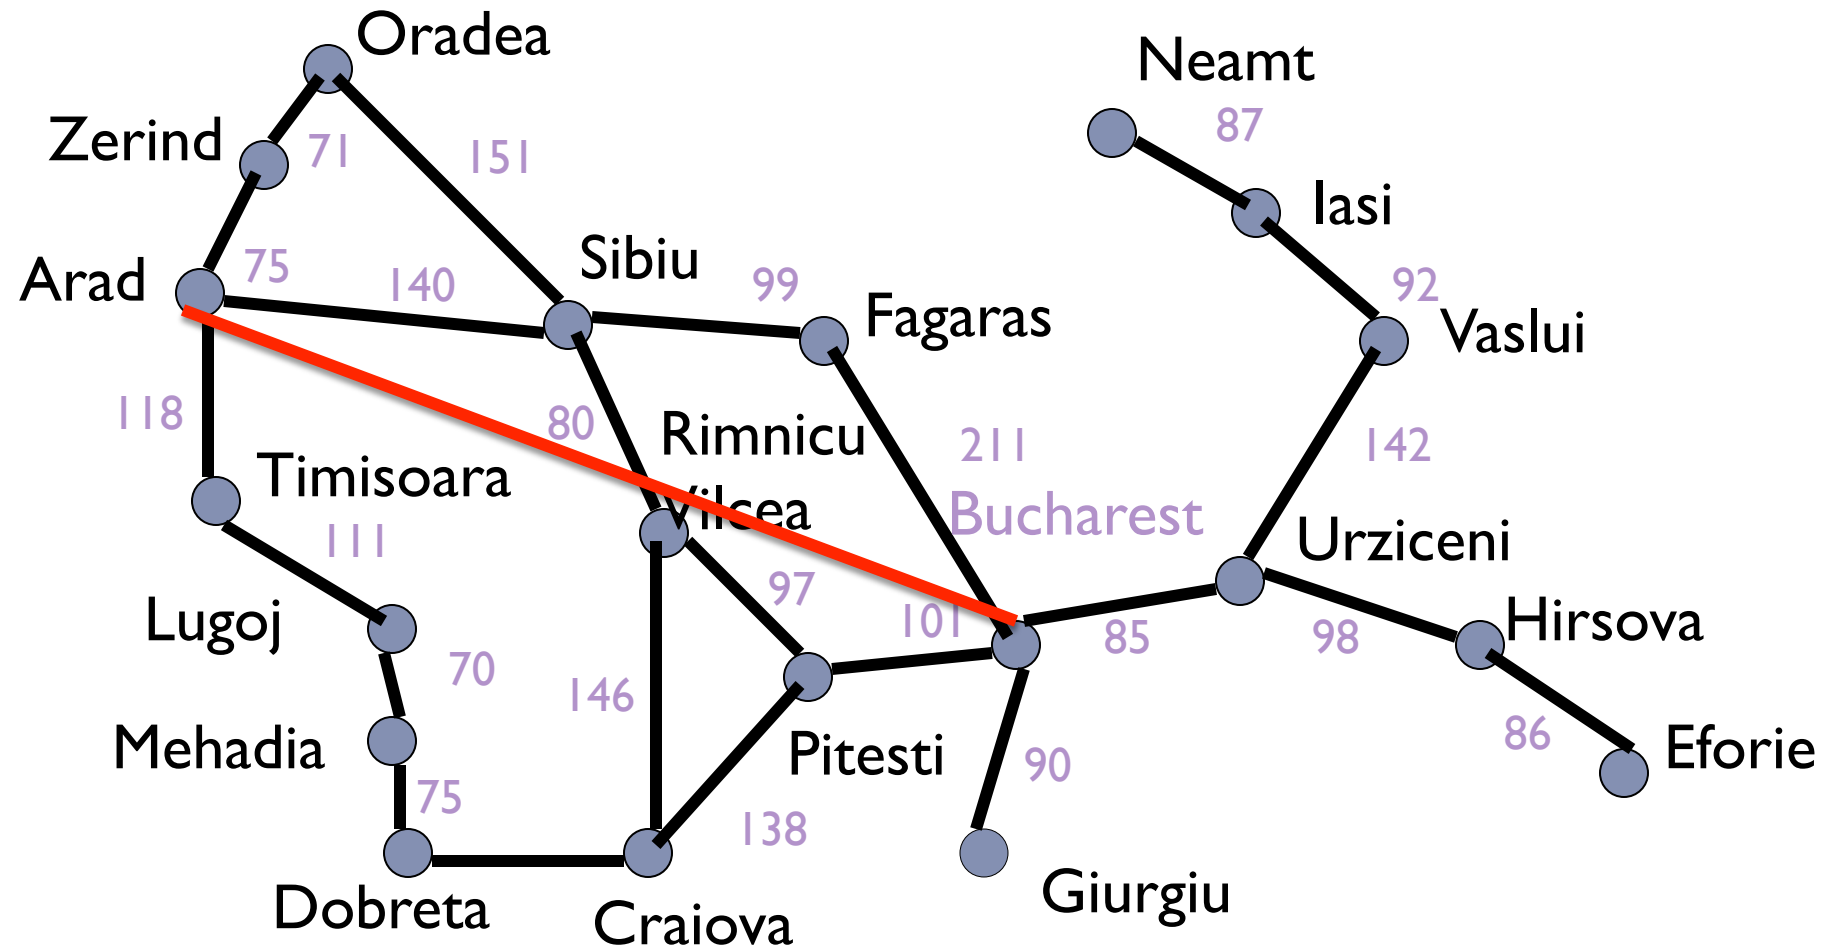

# Designing consistent heuristics

---

- ▶ Consistent heuristics are often solutions to relaxed versions of the original problem.
  - ▶ Manhattan distance in a maze is a relaxed version of the original problem where we allow the agent to move through maze walls.
  - ▶ Euclidean distance in route planning is a relaxed version of the original problem where we allow the agent to travel in a straight line between two nodes regardless of whether there is a road between the nodes.
- ▶ Few general recipes for making consistent heuristics; many of them problem-specific and require deep understanding of the search space.

# Straight line distance

# Using relaxation to design $h(n)$

7	2	4
5		6
8	3	1

Start state

	1	2
3	4	5
6	7	8

Goal state

$h(n)$  = number of moves to  
move from state  $n$  to  
goal state

Idea # 1:  $h(n)$  = number of tiles out of place

1.  $h(\text{start}) = ?$
2. Relax original problem into a set of 8 independent subproblems.

# How good is the heuristic?

---

- ▶ We measure effectiveness of a heuristic by comparing the number of nodes expanded by A\* using that heuristic against the number of nodes expanded by UCS.

	8 step solution	12 step solution
A*+misplaced tiles	39	227
Uniform cost	6300	$3.6 \times 10^6$

Slide adapted from P.Abeel

# Using relaxation to design $h(n)$

7	2	4

8	3	1

Start state

	1	2
3	4	5
6	7	8

Goal state

$$h(\text{start}) = 3 + 1 + 2 + 2 + 2 + 3 + 3 + 2 = 18$$

Idea # 2:  $h(n)$  = sum of Manhattan distance each tile has to move to get to final position

I. What problem relaxation is it based on?

# How good is the heuristic?

---

- ▶ We can also compare the effectiveness of two heuristics by comparing the number of nodes expanded by A\* using each heuristic.

	8 step solution	12 step solution
A*+total manhattan distance	25	73
A*+misplaced tiles	39	227

Slide adapted from P.Abeel

# Another consistent heuristic

---

- ▶  $h(n)$  = actual cost of moving from state  $n$  to goal state
- ▶ Is it a practical heuristic?
  - ▶ Tradeoff between work to estimate  $h(n)$  and the gains obtained in reduction of number of nodes expanded by  $A^*$

# Combining heuristics

---

- ▶ If  $h_1(s)$  and  $h_2(s)$  are consistent heuristics, is  $h_1(s)+h_2(s)$  consistent?
- ▶ If  $h_1(s)$  and  $h_2(s)$  are consistent heuristics, is  $\max(h_1(s), h_2(s))$  consistent?

# Summary

---

- ▶ Uniform cost search is complete, optimal,  $O(\text{size of state space})$  in space and time complexity
- ▶ Informed search: using heuristics
  - ▶ Greedy search is complete, not optimal,  $O(\text{size of state space})$  in space and time complexity
  - ▶ A\* is complete, optimal (with consistent heuristic),  $O(\text{size of state space})$  in space and time complexity. Is a special case of UCS with a modified edge cost function.
  - ▶ Actual performance: function of  $h(n)$
- ▶ Heuristic design: relaxation of original problem
  - ▶ The closer the heuristic is to the actual cost of getting to the goal, while still a remaining an underestimate, the fewer nodes A\* expands in the search for a plan/sequence of actions.
